

Configuration Management Plan

1. Versioning methods & tools

We are using Github and SourceTree to handle our repository. Not all our documents are under version control. So there isn't a version control for the project proposal and the system specification, because we are writing them on Google docs, where more people can concurrently apply changes on the same document.

2. Organization of artifacts

01_ProjectPlanning: Here is the effort estimation stored.

02_Requirements: Requirements document inside

03_Development: Source code project inside here

04_Testing: Everything we want to try comes here

05_ReleaseDoc: Release information

06_MeetingMinutes: Everything we discuss about the project

07_Misc: All stuff that doesn't fit with the other artifacts, like the project proposal, design documents,

3. Variant Management

We also want to use branching which is given in the presentation. So we have the master branch. The master branch has an development branch and the development branch which has feature branches. Our Version will have 3 positions like 1.0.0. The last digit will change when a new feature is done. The second will change when the new features are merged and the first number will change when the whole project is finished.
